

HO-6: Creating XML Documents

You need to store data in an XML document that will be used in a Messaging software application. Messages will be transferred via a wireless connection from a desktop PC to a web server and vice versa.

A message has the following elements: message, to (to whom the message is addressed to), from (the originator of the message), the subject and the text of the message.

The message element has an id attribute and the to and from elements both have 2 attributes: firstname and surname.

Create the xml document with 3 messages and then validate your XML by using the validators highlighted in the previous hands-on exercise.
